# Chapter 5: Link layer

## *our goals:*

- ❖ understand principles behind link layer services:
  - error detection, correction
  - sharing a broadcast channel: multiple access
  - link layer addressing
  - local area networks: Ethernet, VLANs
- ❖ instantiation, implementation of various link layer technologies

# Link layer, LANs: outline

5.1 introduction, services

5.2 error detection,  
correction

5.3 multiple access  
protocols

5.4 LANs

- addressing, ARP
- Ethernet
- switches
- VLANs

5.5 link virtualization:  
MPLS

5.6 data center  
networking

5.7 a day in the life of a  
web request

# Link layer: introduction

## *terminology:*

- ❖ hosts and routers: **nodes**
- ❖ communication channels that connect adjacent nodes along communication path: **links**
  - wired links
  - wireless links
  - LANs
- ❖ layer-2 packet: **frame**, encapsulates datagram

*data-link layer* has responsibility of transferring datagram from one node to *physically adjacent* node over a link

# Link layer: context

- ❖ datagram transferred by different link protocols over different links:
  - e.g., Ethernet on first link, frame relay on intermediate links, 802.11 on last link
- ❖ each link protocol provides different services
  - e.g., may or may not provide rdt over link

## *transportation analogy:*

- ❖ trip from Princeton to Lausanne
  - limo: Princeton to JFK
  - plane: JFK to Geneva
  - train: Geneva to Lausanne
- ❖ tourist = **datagram**
- ❖ transport segment = **communication link**
- ❖ transportation mode = **link layer protocol**
- ❖ travel agent = **routing algorithm**

# Link layer services

## ❖ *framing, link access:*

- encapsulate datagram into frame, adding header, trailer
- channel access if shared medium
- “MAC” addresses used in frame headers to identify source, dest
  - different from IP address!

## ❖ *reliable delivery between adjacent nodes*

- we learned how to do this already (chapter 3)!
- seldom used on low bit-error link (fiber, some twisted pair)
- wireless links: high error rates
  - *Q*: why both link-level and end-end reliability?

# Link layer services (more)

## ❖ *flow control:*

- pacing between adjacent sending and receiving nodes

## ❖ *error detection:*

- errors caused by signal attenuation, noise.
- receiver detects presence of errors:
  - signals sender for retransmission or drops frame

## ❖ *error correction:*

- receiver identifies *and corrects* bit error(s) without resorting to retransmission

## ❖ *half-duplex and full-duplex*

- with half duplex, nodes at both ends of link can transmit, but not at same time

# Where is the link layer implemented?

- ❖ in each and every host
- ❖ link layer implemented in “adaptor” (aka *network interface card* NIC)
  - Ethernet card, 802.11 card; Ethernet chipset
  - controller (single chip) implements link, physical layer
- ❖ attaches into host's system buses (looks like any I/O)
- ❖ combination of hardware, software, firmware

# Adaptors communicating

## ❖ sending side:

- encapsulates datagram in frame
- adds error checking bits, rdt, flow control, etc.

## ❖ receiving side

- looks for errors, rdt, flow control, etc
- extracts datagram, passes to upper layer at receiving side

# Link layer, LANs: outline

5.1 introduction, services

5.2 error detection,  
correction

5.3 multiple access  
protocols

5.4 LANs

- addressing, ARP
- Ethernet
- switches
- VLANs

5.5 link virtualization:  
MPLS

5.6 data center  
networking

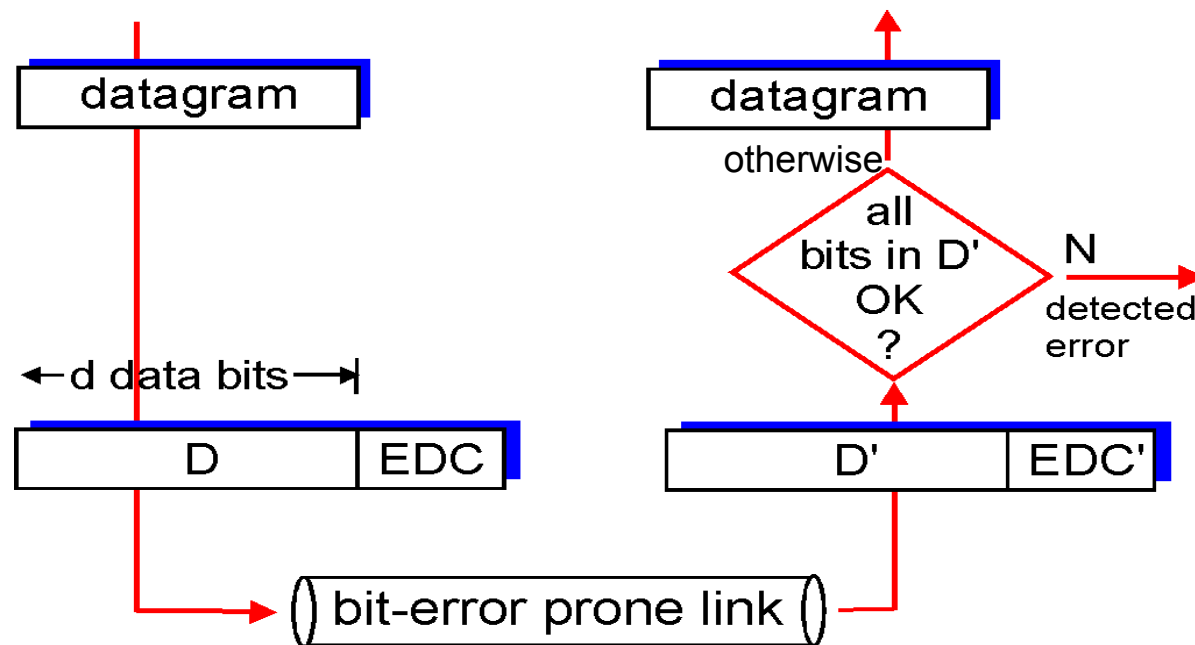

5.7 a day in the life of a  
web request

# Error detection

EDC= Error Detection and Correction bits (redundancy)

D = Data protected by error checking, may include header fields

- Error detection not 100% reliable!
  - protocol may miss some errors, but rarely
  - larger EDC field yields better detection and correction

# Parity checking

## single bit parity:

- ❖ detect single bit errors
- ❖ example of even parity:

### Questions:

- Can errors go undetected?
- How to deal with burst errors?
- Detection vs correction

## two-dimensional bit parity:

- ❖ detect and correct single bit errors

1	0	1	0	1	1
1	1	1	1	0	0
0	1	1	1	0	1
0	0	1	0	1	0

*no errors*

1	0	1	0	1	1
1	1	1	1	0	0
0	1	1	1	0	1
0	0	1	0	1	0

parity error

*correctable  
single bit error*

# Internet checksum (review)

*goal:* detect “errors” (e.g., flipped bits) in transmitted packet  
(note: used at transport layer *only*)

## *sender:*

- ❖ treat segment contents as sequence of 16-bit integers
- ❖ checksum: addition (1's complement sum) of segment contents
- ❖ sender puts checksum value into UDP checksum field

## *receiver:*

- ❖ compute checksum of received segment
- ❖ check if computed checksum equals checksum field value:
  - NO - error detected
  - YES - no error detected.  
*But maybe errors nonetheless?*

## Comments:

- ❖ Simple/fast thus implemented in software (vs. dedicated hardware for CRC)
- ❖ Low overhead but weak protection
- ❖ Checksum used in transport/IP layer, CRC implemented in link layer

# Cyclic redundancy check (CRC)

- ❖ more powerful error-detection coding
- ❖ view data bits, **D**, as a binary number (or as a polynomial)
- ❖ choose  $r+1$  bit pattern (generator), **G**, starting with 1
- ❖ goal: choose  $r$  CRC bits, **R**, such that
  - $\langle D, R \rangle$  exactly divisible by  $G$  (modulo 2)
  - receiver knows  $G$ , divides  $\langle D, R \rangle$  by  $G$ . If non-zero remainder: error detected!
  - can detect all burst errors less than  $r+1$  bits
- ❖ widely used in practice (Ethernet, 802.11 WiFi, ATM)

$$D * 2^r \text{ XOR } R$$

*mathematical formula*

# CRC example

want:

$$D \cdot 2^r \text{ XOR } R = nG$$

equivalently:

$$D \cdot 2^r = nG \text{ XOR } R$$

equivalently:

if we divide  $D \cdot 2^r$  by  $G$ , want remainder  $R$  to satisfy:

$$R = \text{remainder}\left[\frac{D \cdot 2^r}{G}\right]$$

*All operations are modulo 2 arithmetic ( $GF(2)$ ) c, without carries in addition or borrows in subtraction.*

# CRC

- ❖ Can detect up to  $r$  burst errors, for sure.
- ❖ Can detect any odd number of bit errors.
- ❖ (Under assumptions) can detect burst of length  $>r+1$  w.p.  $1-0.5^r$
- ❖ The longer  $G$ , the stronger the protection, the higher the overhead and computation
- ❖ Typically
  - ❖ CRC: 32 bits, generators standardized
  - ❖ needs dedicated hardware
  - ❖ used at the link layer

$$R = \text{remainder}\left[\frac{D \cdot 2^r}{G}\right]$$
