## Chapter 4: outline

- 4.1 introduction
- 4.2 virtual circuit and datagram networks
- 4.3 what's inside a router
- 4.4 IP: Internet Protocol
  - datagram format
  - IPv4 addressing
  - ICMP
  - IPv6

- 4.5 routing algorithms
  - link state
  - distance vector
  - hierarchical routing
- 4.6 routing in the Internet
  - RIP
  - OSPF
  - BGP
- 4.7 broadcast and multicast routing

### The Internet network layer

host, router network layer functions:

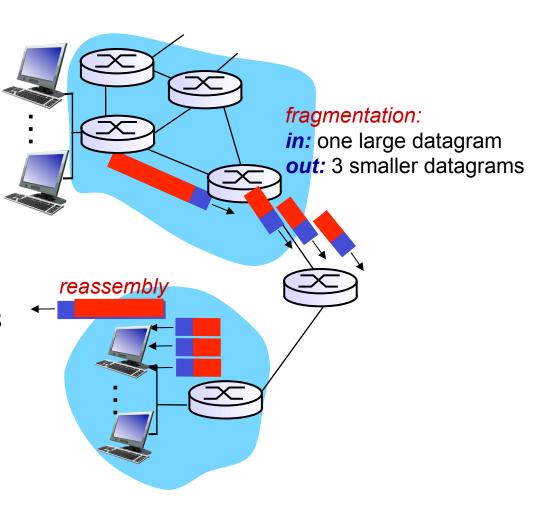

### IP datagram format

layer overhead

IP protocol version 32 bits total datagram number length (bytes) ver head type of header length length (bytes) service for "type" of datafragment 16-bit identifier | flgs ·fragmentation/ offset reassembly max number time to upper header remaining hops live layer checksum (decremented at 32 bit source IP address each router) 32 bit destination IP address upper layer protocol to deliver payload to e.g. timestamp, options (if any) record route data taken, specify how much overhead? (variable length, list of routers 20 bytes of TCP typically a TCP to visit. 20 bytes of IP or UDP segment) = 40 bytes + app

## IP fragmentation, reassembly

- network links have MTU (max.transfer size) largest possible link-level frame
  - different link types, different MTUs
- large IP datagram divided ("fragmented") within net
  - one datagram becomes several datagrams
  - "reassembled" only at final destination
  - IP header bits used to identify, order related fragments

## IP fragmentation, reassembly

ID: unique per packet, offset: multiple of 8. incremented by sending host length ID fragflag offset =4000 l **=**x =0example: =0 4000 byte datagram one large datagram becomes MTU = 1500 bytes several smaller datagrams 1480 bytes in length | fragflag offset data fieldy =1500 **=**X =1 =0length | offset = fragflag ID offset 1480/8 =1500 **=**X =185 =1 offset = length fragflag offset 2\*1480/8 =1040  $=\chi$ =370 =0

Original datagram: 20+3980=4000

1st fragment: 20+1480= 1500 starts at byte 0

2<sup>nd</sup> fragment: 20+1480 = 1500 starts at byte 185\*8=1480 3<sup>rd</sup> fragment: 20+1020 = 1040 starts at byte (185+185)\*8=2960

Data: 1480+1480+1020=3980

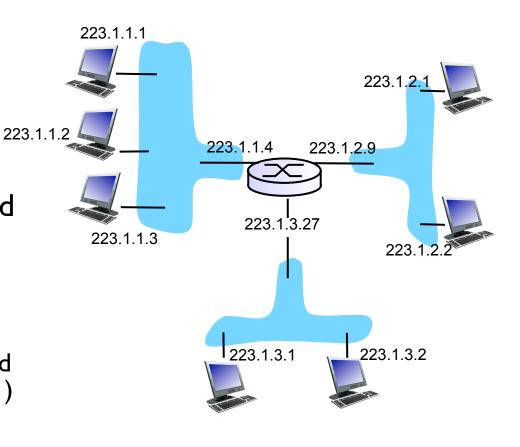

## Chapter 4: outline

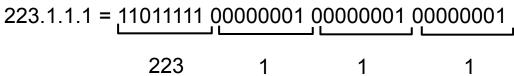

- 4.1 introduction
- 4.2 virtual circuit and datagram networks
- 4.3 what's inside a router
- 4.4 IP: Internet Protocol
  - datagram format
  - IPv4 addressing
  - ICMP
  - IPv6

- 4.5 routing algorithms
  - link state
  - distance vector
  - hierarchical routing
- 4.6 routing in the Internet
  - RIP
  - OSPF
  - BGP
- 4.7 broadcast and multicast routing

### IP addressing: introduction

- IP address: 32-bit identifier for host or router interface
- interface: connection between host/router and physical link
  - router's typically have multiple interfaces
  - host typically has one or two interfaces (e.g., wired Ethernet, wireless 802.11)
- IP addresses associated with each interface

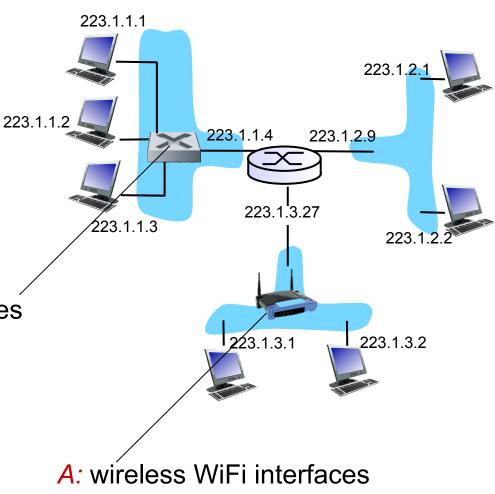

### IP addressing: introduction

Q: how are interfaces actually connected?

A: we'll learn about that in chapter 5, 6.

A: wired Ethernet interfaces connected by Ethernet switches

For now: don't need to worry about how one interface is connected to another (with no intervening router)

connected by WiFi base station

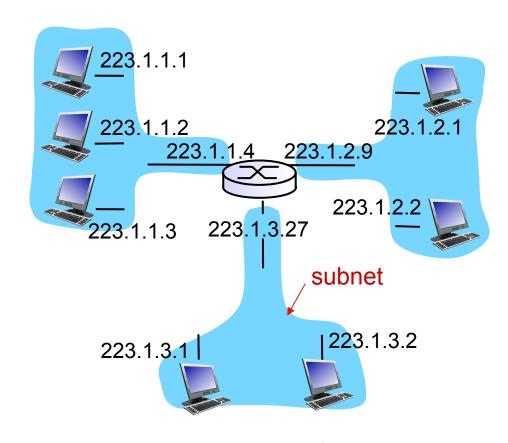

### Subnets

#### \*IP address:

- subnet part high order bits
- host part low order bits

#### \*what's a subnet ?

- device interfaces with same subnet part of IP address
- can physically reach each other without intervening router

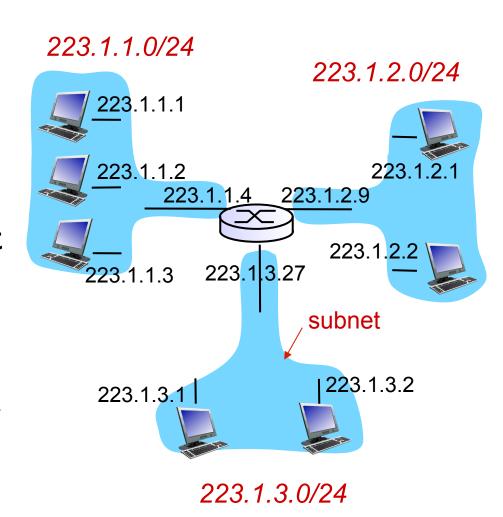

network consisting of 3 subnets

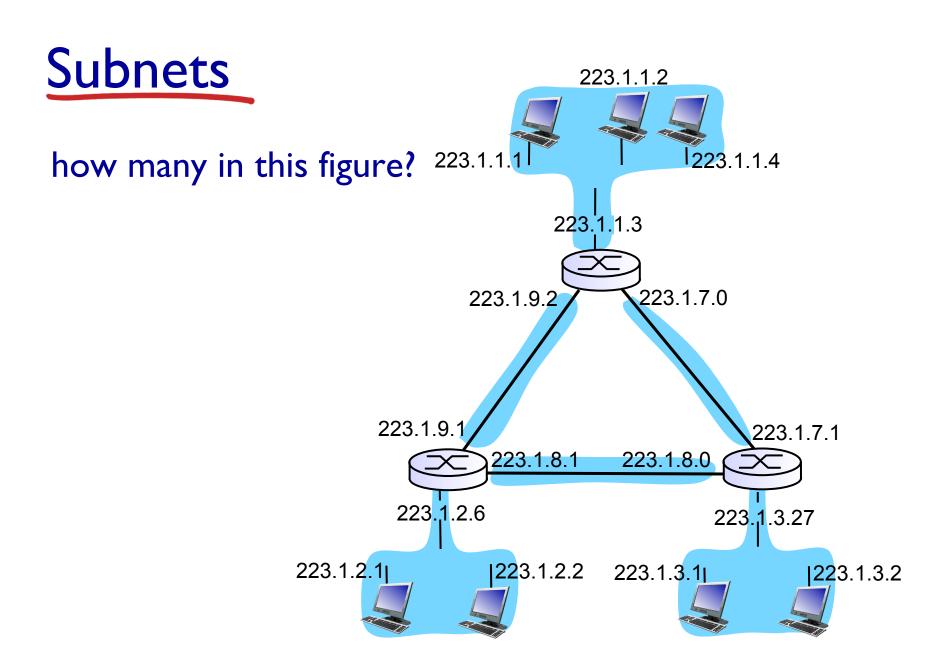

## Subnets

#### recipe

- to determine the subnets, detach each interface from its host or router, creating islands of isolated networks
- each isolated network is called a subnet

subnet mask: /24

#### Historic Classful Network Architecture:

Class	Starting with (bits)	Range of first byte (decimal)	Network id format	Host id format	Number of networks	Numnber of hosts
A	0	0-127	a	b.c.d	2 <sup>7</sup> = 128	2 <sup>24</sup> = 16777216
В	10	128-191	a.b	c.d	2 <sup>14</sup> = 16384	2 <sup>16</sup> = 65536
С	110	192-223	a.b.c	d	$2^{21} = 2097152$	2 <sup>8</sup> = 256

11001000 00010111 00010000 00000000

Class C network ("/24"): 200.23.16.0

Example IP in that network: 200.23.16.1

## (Since 1993) IP addressing: CIDR

#### CIDR: Classless InterDomain Routing

- subnet portion of address of arbitrary length
- address format: a.b.c.d/x, where x is # bits in subnet portion of address

11001000 00010111 00010000 00000000

200.23.16.0/23

Q: what did we gain?

A: more efficient use of the IP address space

## Some special IP addresses

All I's: means "all hosts on this subnet"

200.23.17.255/23

All 0's: means "this subnet"

11001000 00010111 00010000 00000000

200.23.16.0/23

#### More IP addresses

- Reserved IP addresses for special purposes
  - 127.0.0.1: local host
  - Multicast
    - 224.0.0.0/8-239.0.0.0/8
  - Private networks:
    - not routed, typically used through NATs.
    - 24- bit block, /8 prefix, 1xA: 10.0.0.0-10.255.255.255
    - 20-bit block, /12 prefix, 16xB: 172.16.0.0- 172.31.255.255
    - 16-bit block, /16 prefix, 256xC: 192.168.0.0-192.168.255.255
  - Assigned to special institutions

## IP addresses: how to get one?

Q: How does a host get an IP address?

- hard-coded by system admin in a file
  - Windows: control-panel->network->configuration->tcp/ ip->properties
  - UNIX: /etc/rc.config
- DHCP: Dynamic Host Configuration Protocol: dynamically get address from as server
  - "plug-and-play"

#### IP addresses: networks

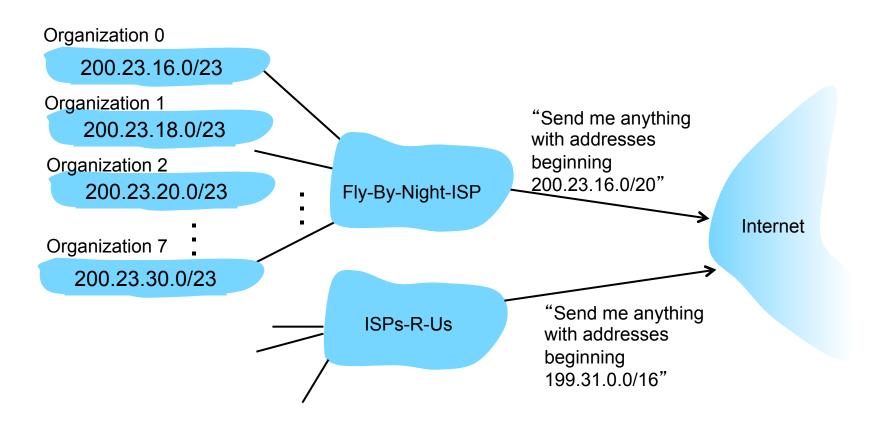

Q: how does network get subnet part of IP addr?

A: gets allocated portion of its provider ISP's address space

ISP's block	11001000	00010111	00010000	00000000	200.23.16.0/20
	44004000	00010111	00040000	0000000	000 00 40 0/00
Organization 0	<u>11001000</u>	00010111	<u>0001000</u> 0	00000000	200.23.16.0/23
Organization 1	<u>11001000</u>	00010111	<u>0001001</u> 0	00000000	200.23.18.0/23
Organization 2	11001000	00010111	<u>0001010</u> 0	00000000	200.23.20.0/23
Organization 7	11001000	00010111	00011110	00000000	200.23.30.0/23

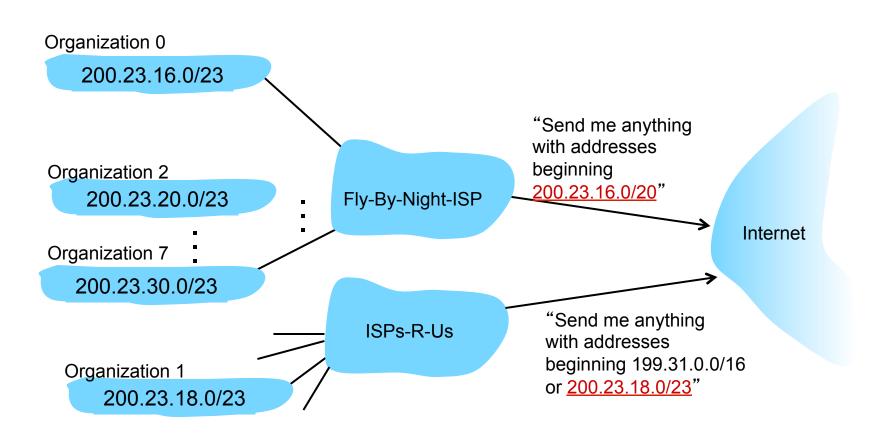

#### Hierarchical addressing: route aggregation

hierarchical addressing allows efficient advertisement of routing information:

#### Hierarchical addressing: more specific routes

#### ISPs-R-Us has a more specific route to Organization I

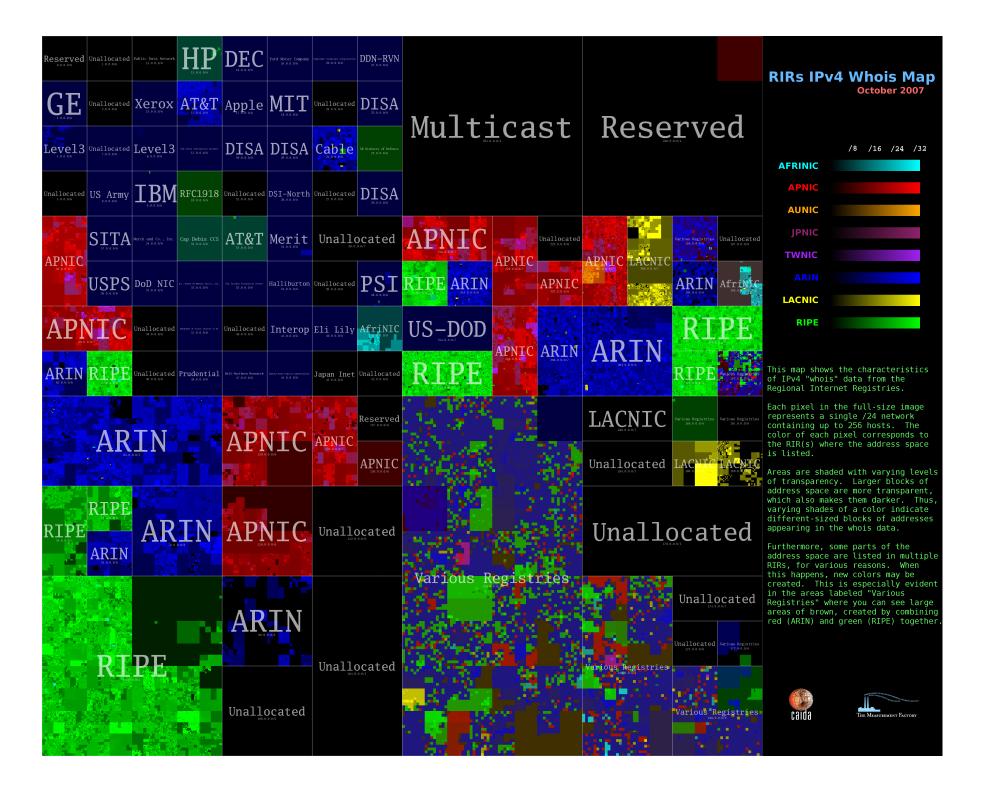

#### IP addressing: ISPs

- Q: how does an ISP get block of addresses?
- A: ICANN: Internet Corporation for Assigned Names and Numbers http://www.icann.org/
  - allocates addresses
  - manages DNS
  - assigns domain names, resolves disputes
  - delegates to regional registries (RIRs)

### IP addresses: a scarce resource!

- More users than IP addresses
  - In the 1970's: 2<sup>32</sup> was plenty of addresses
  - ~2010: IB computers, 5B phones
- Bad utilization
  - Some prefixes are full
  - Some are reserved and unused!
- How are they allocated today?
  - http://en.wikipedia.org/wiki/List\_of\_assigned\_/8\_IPv4\_address\_blocks
  - http://www.caida.org/research/id-consumption/whois-map/

#### IP addresses: a scarce resource!

- More users than IP addresses:
  - In the 1970's: 2<sup>32</sup> was plenty of addresses
  - Today: IB computers, 5B phones
- Bad utilization of existing IP addresses
  - Some prefixes are full
  - Some are reserved and unused!
  - CAIDA's map

#### Solutions:

- DHCP: get an IP dynamically, when you use it
- NAT: entire subnet uses one IP externally
- IPv6: increase the IP address from 32 to 64 bits.

#### DHCP: Dynamic Host Configuration Protocol

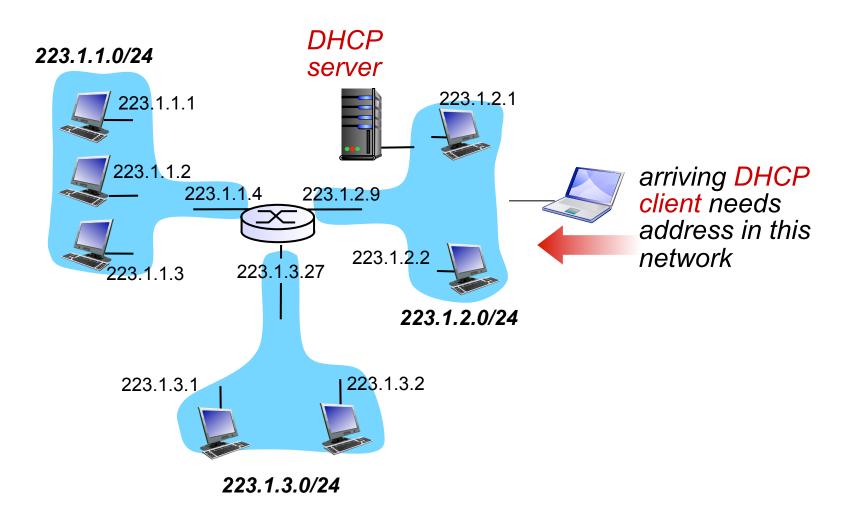

goal: allow host to dynamically obtain its IP address from network server when it joins network

- can renew its lease on address in use
- allows reuse of addresses (only hold address while connected/"on")
- support for mobile users who want to join network

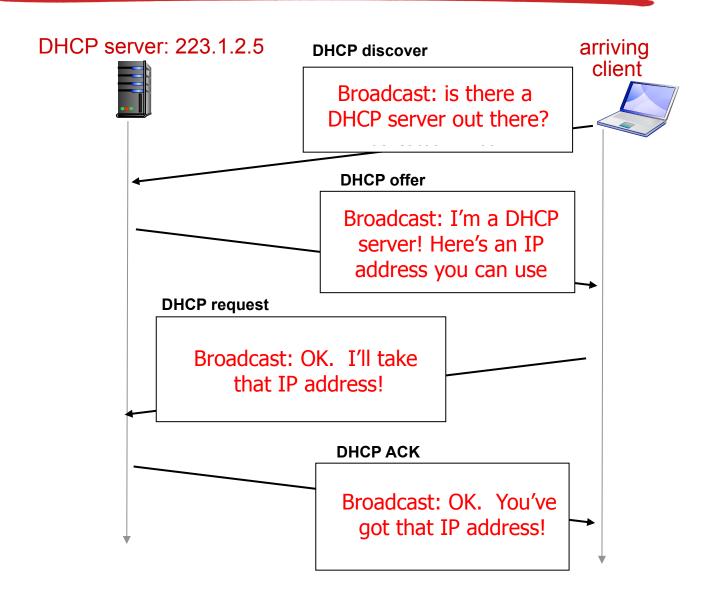

#### **DHCP** overview:

- host broadcasts "DHCP discover" msg [optional]
- DHCP server responds with "DHCP offer" msg [optional]
- host requests IP address: "DHCP request" msg
- DHCP server sends address: "DHCP ack" msg

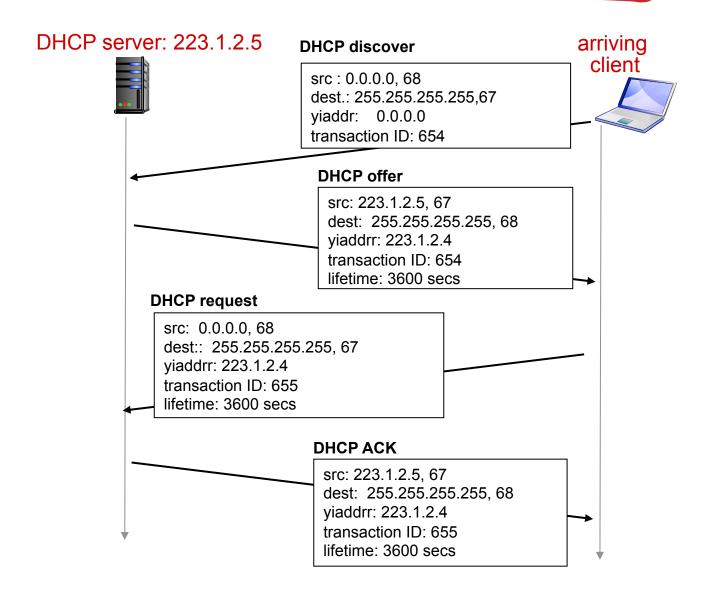

#### DHCP client-server scenario

### DHCP client-server scenario

#### DHCP client-server scenario

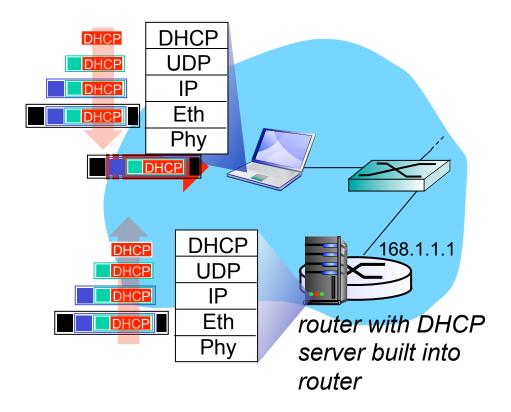

#### DHCP: more than IP addresses

## DHCP can return more than just allocated IP address on subnet:

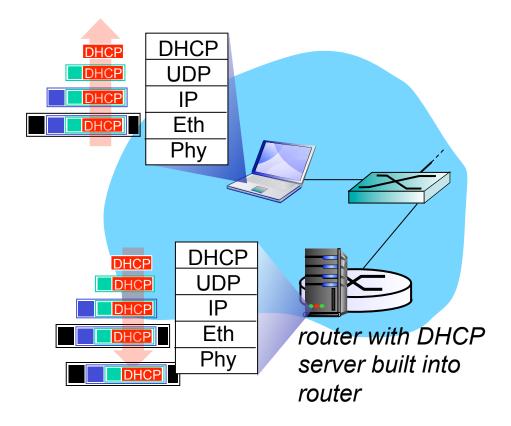

- address of first-hop router for client
- name and IP address of local DNS server
- network mask (indicating network versus host portion of address)

#### DHCP: example

- connecting laptop needs its IP address, addr of first-hop router, addr of DNS server: use DHCP
- DHCP request encapsulated in UDP, encapsulated in IP, encapsulated in 802. I Ethernet
- Ethernet demuxed to IP demuxed, UDP demuxed to DHCP

#### DHCP: example

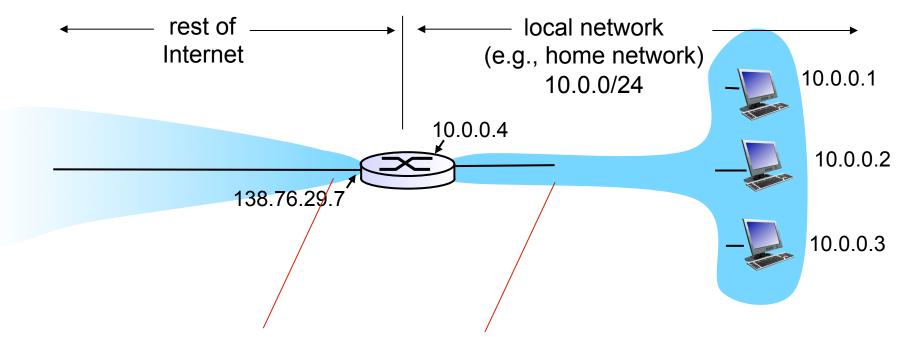

- DCP server formulates DHCP ACK containing client's IP address, IP address of first-hop router for client, name & IP address of DNS server
- encapsulation of DHCP server, frame forwarded to client, demuxing up to DHCP at client
- client now knows its IP address, name and IP address of DSN server, IP address of its first-hop router

# [DHCP: Wireshark output (home LAN)]

Option: (t=15,l=20) Domain Name = "hsd1.ma.comcast.net."
```

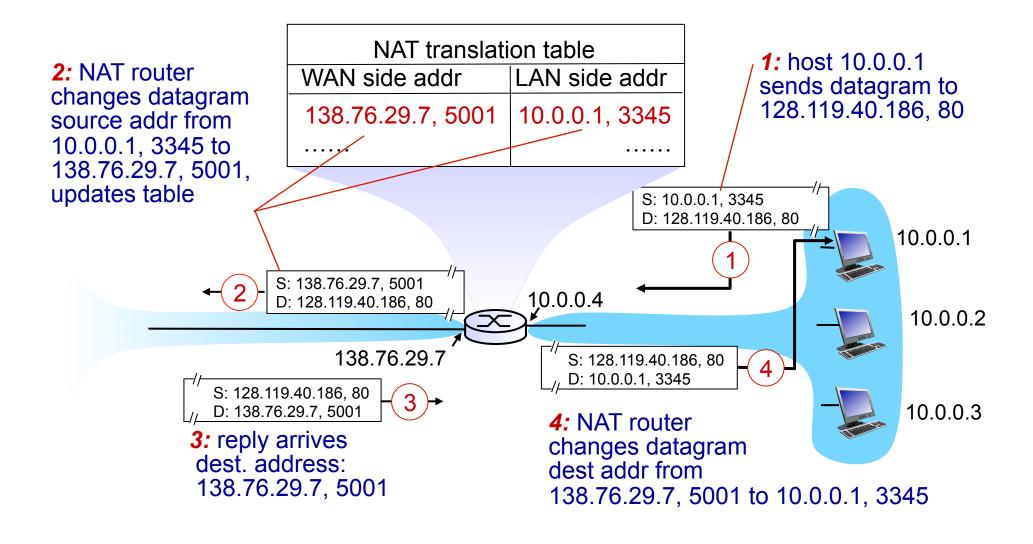

all datagrams leaving local network have same single source NAT IP address: 138.76.29.7, different source port numbers datagrams with source or destination in this network have 10.0.0/24 address for source, destination (as usual)

motivation: local network uses just one IP address as far as outside world is concerned:

- range of addresses not needed from ISP: just one IP address for all devices
- can change addresses of devices in local network without notifying outside world
- can change ISP without changing addresses of devices in local network
- devices inside local net not explicitly addressable, visible by outside world (a security plus)

#### implementation: NAT router must:

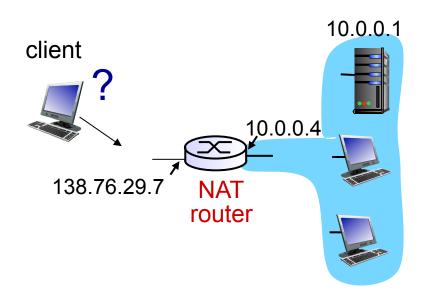

- outgoing datagrams: replace (source IP address, port #) of every outgoing datagram to (NAT IP address, new port #)
   ... remote clients/servers will respond using (NAT IP address, new port #) as destination addr
- remember (in NAT translation table) every (source IP address, port #) to (NAT IP address, new port #) translation pair
- incoming datagrams: replace (NAT IP address, new port #) in dest fields of every incoming datagram with corresponding (source IP address, port #) stored in NAT table

- 16-bit port-number field:
  - 60,000 simultaneous connections with a single LAN-side address!
- NAT is controversial:
  - routers should only process up to layer 3
  - violates end-to-end argument
    - NAT possibility must be taken into account by app designers, e.g., P2P applications

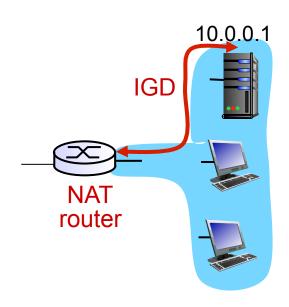

### NAT traversal problem

- client wants to connect to server with address 10.0.0.1
  - server address [0.0.0.] local to LAN (client can't use it as destination addr)
  - only one externally visible NATed address: 138.76.29.7
- solution I: statically configure NAT to forward incoming connection requests at given port to server
  - e.g., (138.76.29.7, port 2500)
     always forwarded to 10.0.0.1 port 25000

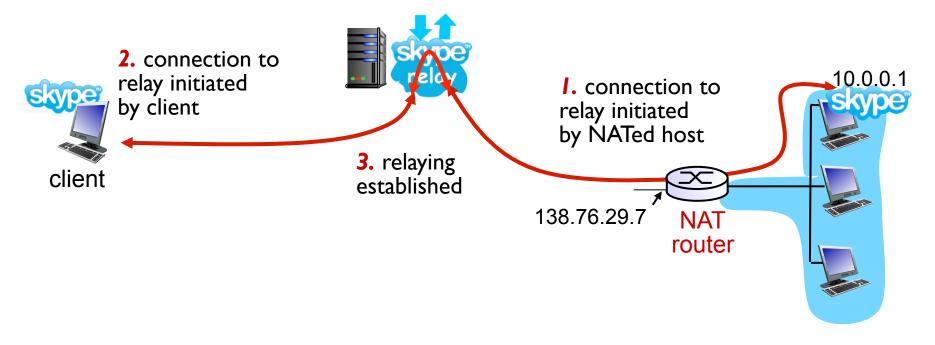

#### NAT traversal problem

- solution 2: Universal Plug and Play (UPnP) Internet Gateway Device (IGD) Protocol. Allows NATed host to:
  - learn public IP address (138.76.29.7)
  - add/remove port mappings (with lease times)
  - i.e., automate static NAT port map configuration

#### NAT traversal problem

- solution 3: relaying (used in Skype)
  - NATed client establishes connection to relay
  - external client connects to relay
  - relay bridges packets between to connections

# Chapter 4: outline

- 4.1 introduction
- 4.2 virtual circuit and datagram networks
- 4.3 what's inside a router
- 4.4 IP: Internet Protocol
  - datagram format
  - IPv4 addressing
  - ICMP
  - IPv6

- 4.5 routing algorithms
  - link state
  - distance vector
  - hierarchical routing
- 4.6 routing in the Internet
  - RIP
  - OSPF
  - BGP
- 4.7 broadcast and multicast routing

#### ICMP: internet control message protocol

*	used by hosts & routers to communicate network-level information	<u>Type</u> 0 3	Code 0 0	description echo reply (ping) dest. network unreachable
	error reporting:	3	1	dest host unreachable
	unreachable host, network,	3	2	dest protocol unreachable
	port, protocol	3	3	dest port unreachable
	<ul><li>echo request/reply (used by</li></ul>	3	6	dest network unknown
	ping)	3	7	dest host unknown
*	network-layer "above" IP:	4	0	source quench (congestion
	<ul><li>ICMP msgs carried in IP</li></ul>			control - not used)
	datagrams	8	0	echo request (ping)
		9	0	route advertisement
***	ICMP message: type, code	10	0	router discovery
	plus first 8 bytes of IP	11	0	TTL expired
	datagram causing error	12	0	bad IP header

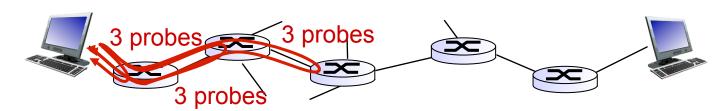

#### Traceroute and ICMP

- source sends series of UDP segments to dest
  - first set has TTL = I
  - second set has TTL=2, etc.
  - unlikely port number
- when nth set of datagrams arrives to nth router:
  - router discards datagrams
  - and sends source ICMP messages (type II, code 0)
  - ICMP messages includes name of router & IP address

 when ICMP messages arrives, source records RTTs

#### stopping criteria:

- UDP segment eventually arrives at destination host
- destination returns ICMP "port unreachable" message (type 3, code 3)
- source stops

#### IPv6: motivation

- initial motivation: 32-bit address space soon to be completely allocated.
- additional motivation:
  - header format helps speed processing/forwarding
  - header changes to facilitate QoS

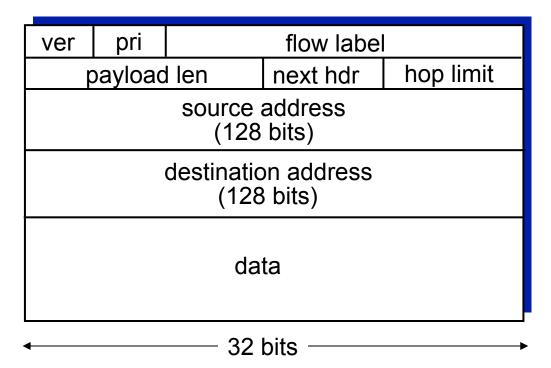

#### IPv6 datagram format:

- fixed-length 40 byte header
- no fragmentation allowed

# IPv6 datagram format

priority: identify priority among datagrams in flow flow Label: identify datagrams in same "flow." (concept of flow not well defined).

next header: identify upper layer protocol for data

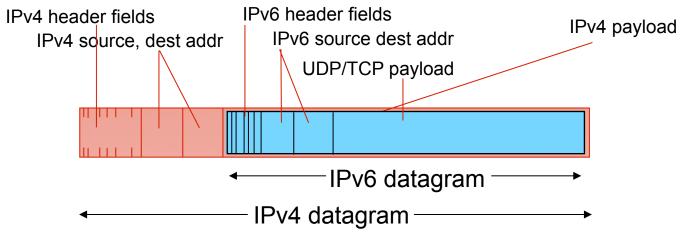

## Other changes from IPv4

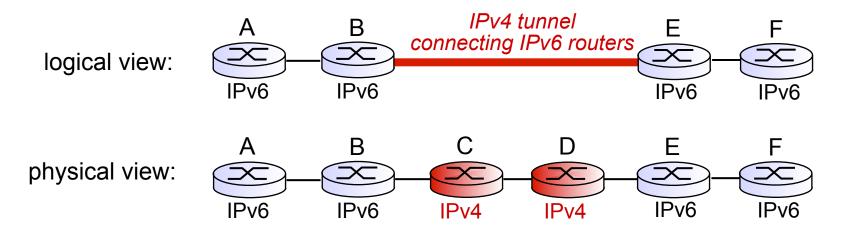

- checksum: removed entirely to reduce processing time at each hop
- options: allowed, but outside of header, indicated by "Next Header" field
- \* ICMPv6: new version of ICMP
  - additional message types, e.g. "Packet Too Big"
  - multicast group management functions

#### Transition from IPv4 to IPv6

- Could we shut down the Internet on Friday on IPv4, upgrade all routers to IPv6, and restart on Monday?
- Not all routers can be upgraded simultaneously. How will network operate with mixed IPv4 and IPv6 routers?
  - Dual Stack:
  - Tunneling: IPv6 datagram carried as payload in IPv4 datagram among IPv4 routers

## **Tunneling**

#### **Tunneling**
